

1. Improve your application UI and other improvisations.

2. Explored the documentation for core components of Langchain

LangChain Documentation – Core Components

I explored the LangChain JavaScript documentation to understand the core components and how they work together.

The main components I found are:

- **Models** – Used to connect and interact with LLMs.
- **Messages** – Handles communication between the user, AI, and tools.

- **Prompts** – Provides instructions and context to the model.
- **Tools** – Allows the AI to perform actions by calling functions or APIs.
- **Agents** – Combines models and tools so the AI can decide what action to take.
- **Structured Output** – Helps get responses in a predefined format such as JSON.
- **Middleware** – Used for additional controls like logging, retries, guardrails, and human approval.
- **Embeddings** – Converts text into vectors for semantic search.
- **Retrievers** – Retrieves relevant information from a knowledge source.
- **Vector Stores** – Stores and searches embeddings, mainly used in RAG.
- **LangGraph** – Used for complex workflows, state management, and advanced agent orchestration.
- **LangSmith** – Used for tracing, debugging, monitoring, and evaluating applications.

Overall understanding:

LangChain provides the building blocks for connecting an **LLM with prompts, tools, knowledge, and workflows** to build AI applications and agents. For our project, the most relevant components are **Models, Prompts, Tools, Agents, Structured Output, Middleware, and LangGraph**.
